Variable definition

Demographics

Age was calculated using the year and month of birth (UK Biobank fields 34 and 52) as of 31 January 2020, when COVID-19 was first diagnosed in the UK. Sex is as defined in field 31. Ethnicity was recoded in three categories from field 21000: White (British, Irish or any other White background), Black (including Caribbean and African background) and Other (Mixed, Asian or other ethnic background).

Social factors

Highest attained qualification is retrieved from field 6138. The housing variables are encoded in fields 670, 680, and 709. The household income (field 738) is recoded in four balanced categories. Occupation is defined from the job code based on the SOC2000 classification (field 132) and the employment status (field 6142) entered at baseline, and recoded as: employed (in paid employment or self-employed) healthcare workers (including health professionals, health and social welfare associate professionals, healthcare and related personal services, health and social service managers and hospital porters), employed non-healthcare workers, unemployed (including studying and doing unpaid voluntary work), and retired.

Health risk factors

Smoking and alcohol drinking status are used as defined in fields 20116 and 20117 respectively. Continuous measurement of the Body Mass Index (BMI) at recruitment is provided in field 21001 and was categorised as: <25, 25–30, 30–40 and >40 kg/m².

Biological variables

Measured levels of total cholesterol in mmol/L (as defined in UK Biobank field ID 30690), high density lipoprotein cholesterol in mmol/L (30760), triglycerides in mmol/L (30870), vitamin D in nmol/L (30890), and cystatin C in mg/L (30720) were taken at baseline.

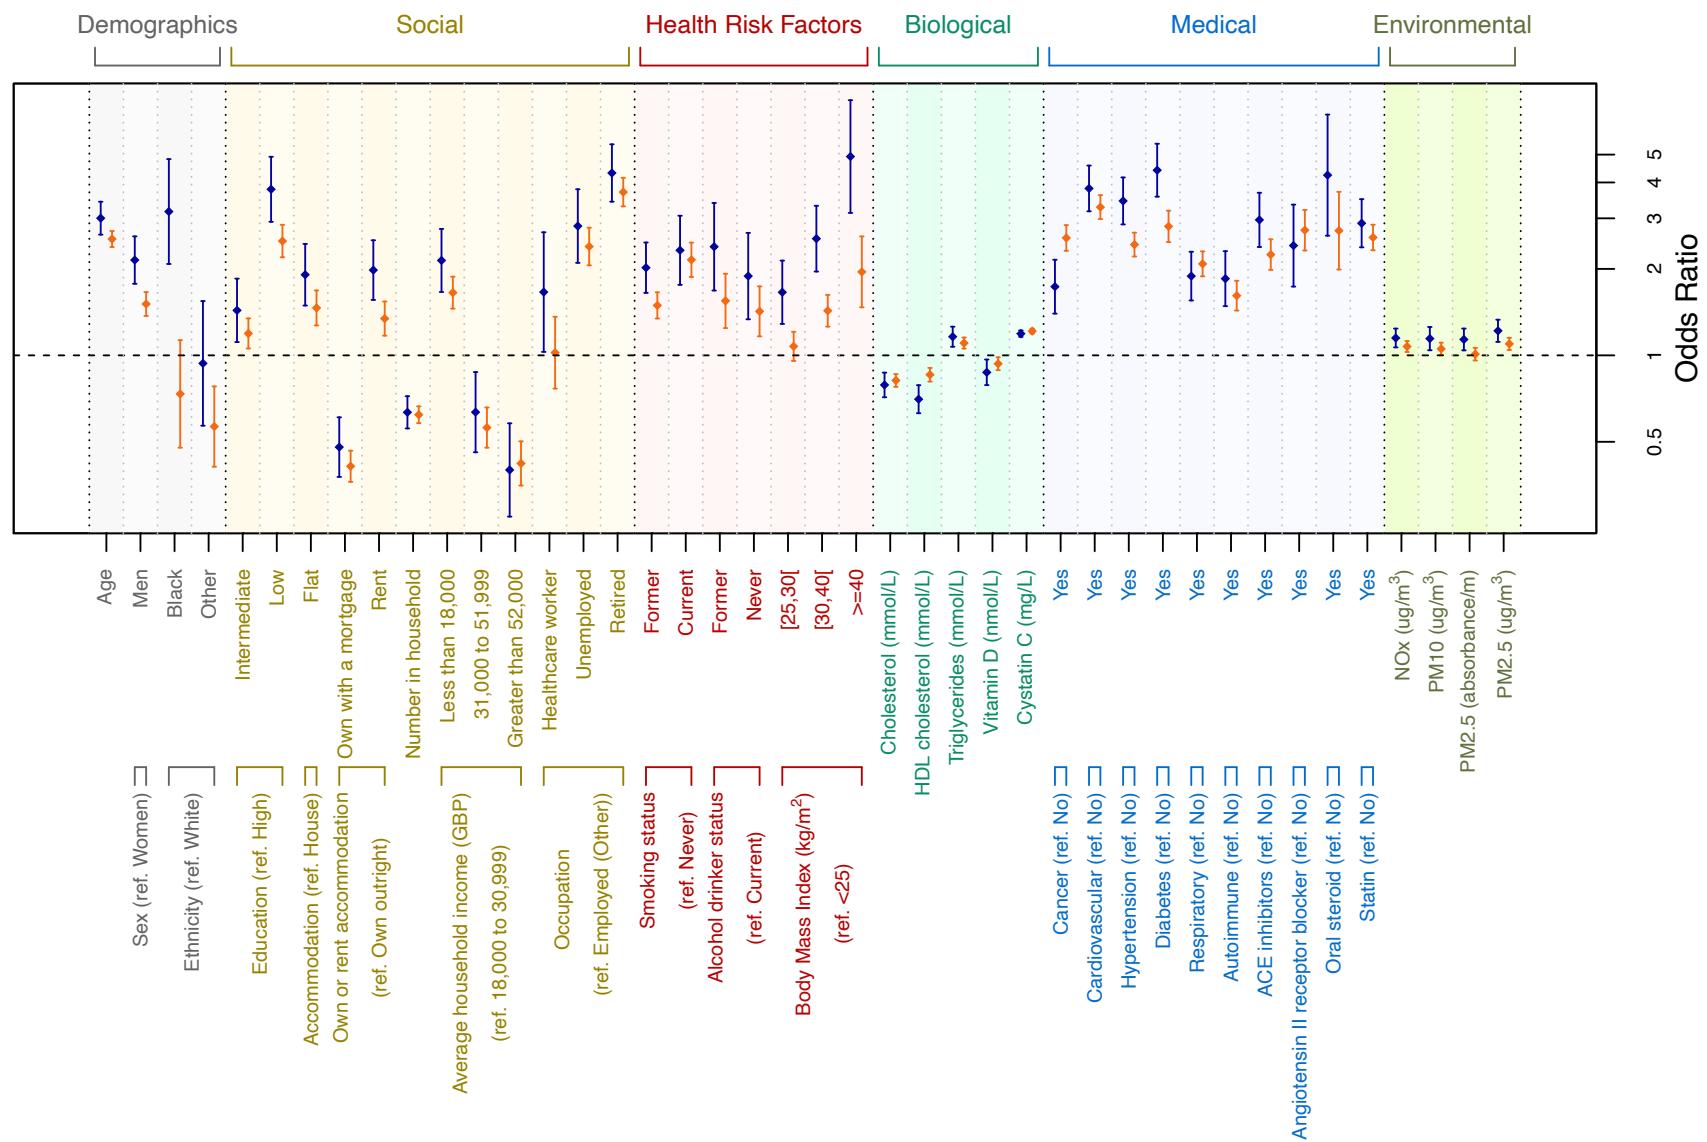

Medical variables

All codes used to define medical variables are available in Supplementary Table 1. Comorbidities (yes/no) were identified either from nurse-administrated questionnaire data at baseline (UK Biobank fields 20001 and 20002) or linked Hospital Episode Statistics (ICD-9 or ICD-10 codes, censored at 31 March 2017). Cancer included any reported or diagnosed non-benign cancer. Diabetes additionally included those with baseline glycated haemoglobin above or equal to 48 mmol/mol. Medication codes were from self-report (UK Biobank field 20003).

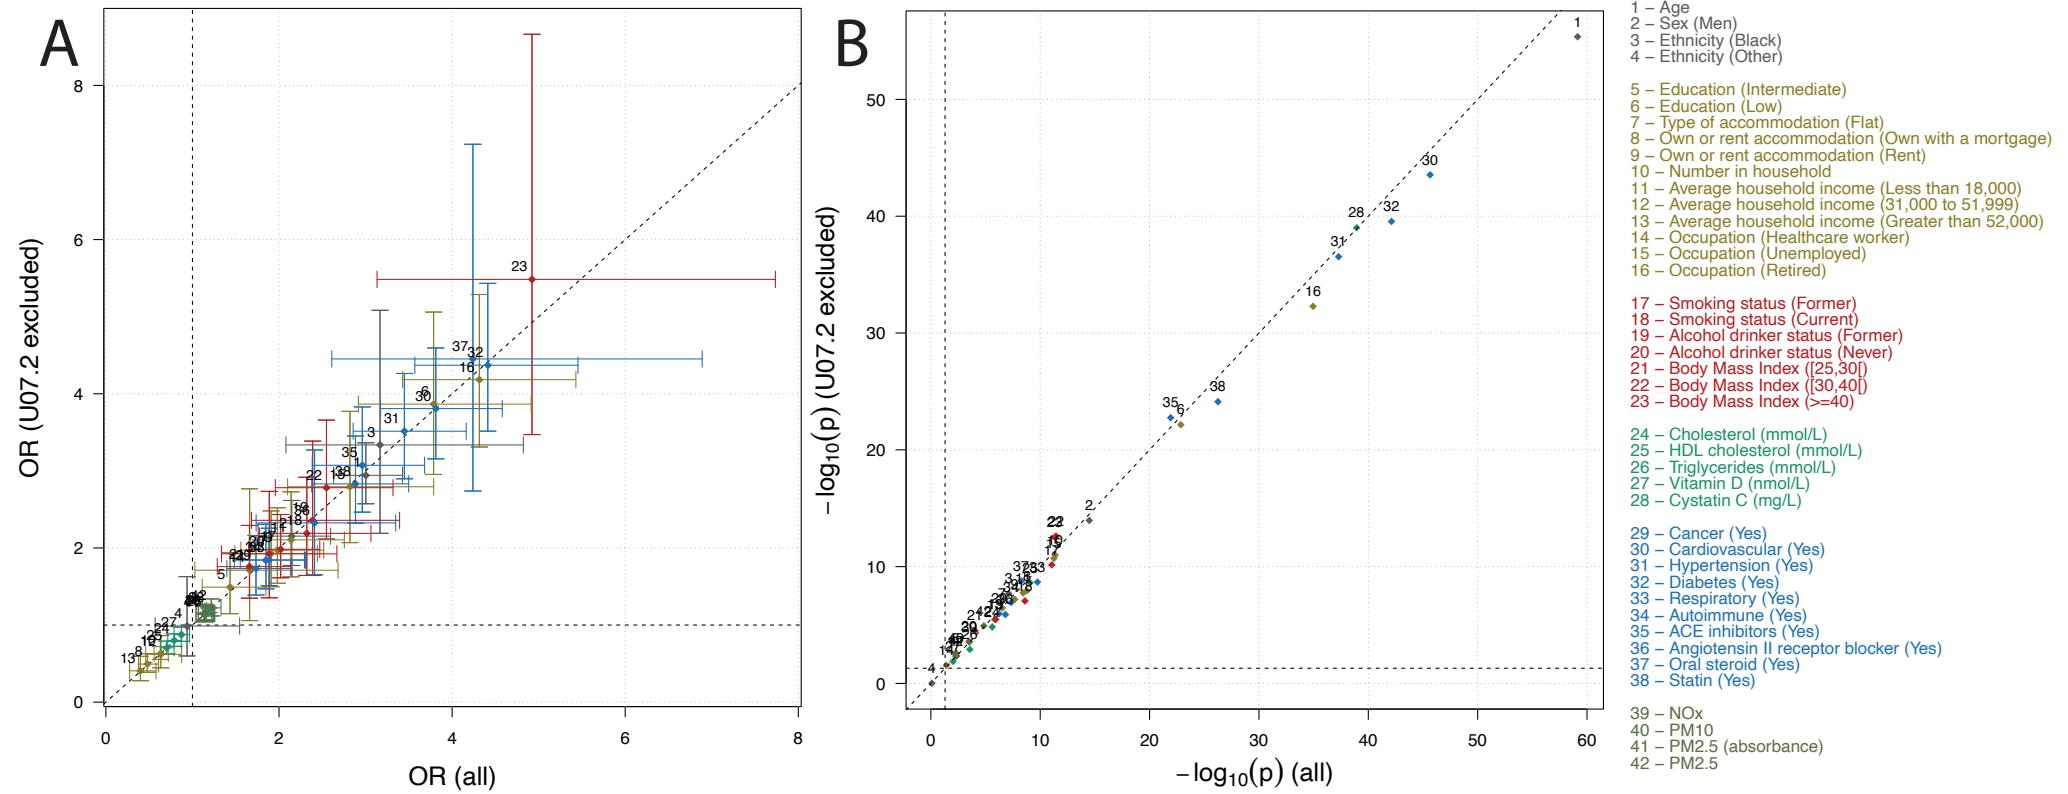

Environmental exposures

Modelled levels of exposures to NO_x, PM10, PM2.5 absorbance and PM2.5 were used as defined in fields 24004, 24005, 24007, and 24006.

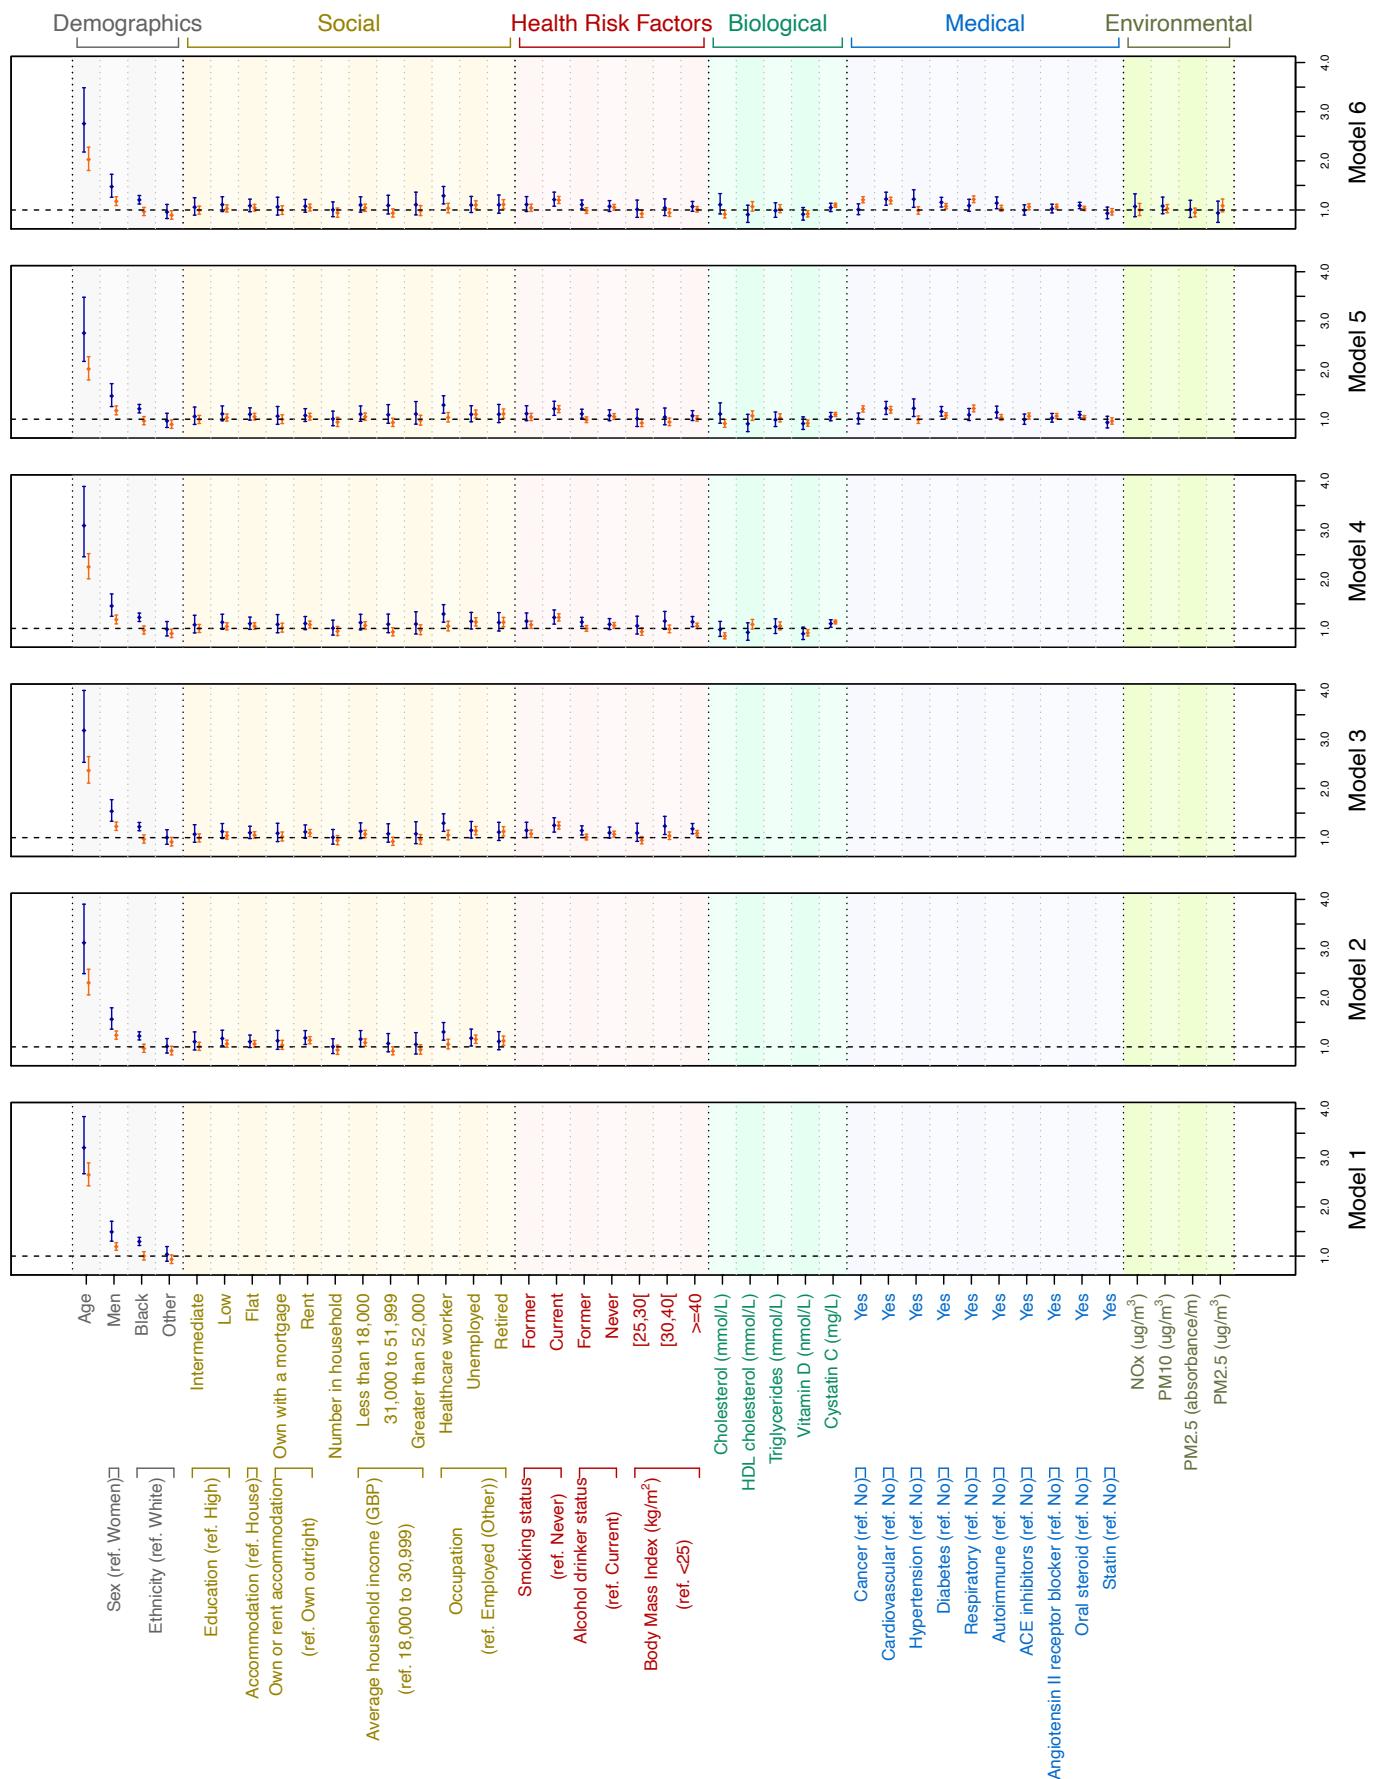

Supplementary Figure 1: Results from the univariate logistic regression models from each covariate separately for the risk of COVID-19 death (in blue) and non-COVID-19 death (in orange). Effect size estimates expressed as odds ratios (ORs) are represented for demographic covariates, and social, health risk, biological, medical, and environmental factors. ORs for continuous variables are standardized to ensure comparability.

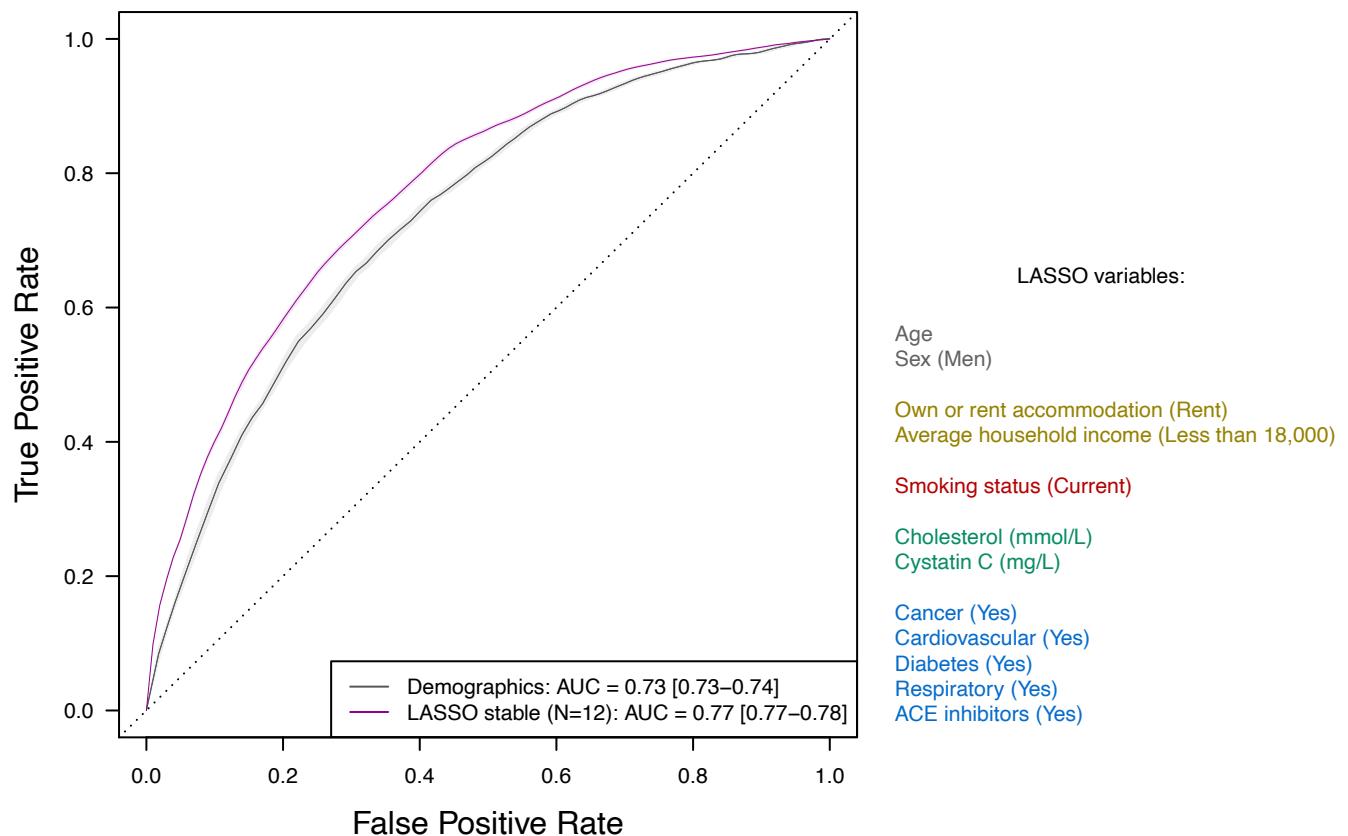

Supplementary Figure 2: Comparison of the odds ratio (A) and p-values (B) from the logistic models of the probability of dying from COVID-19, where the cause of death is defined as U07.1 and U07.2 (X-axis, 459 deaths vs. 470,465 participants alive at the end of follow up), or U07.1 only (Y-axis, 438 deaths vs. 470,465 participants alive at the end of follow up) for demographics (in grey, N=4), social (brown, N=12), health risk (red, N=7), biological (green, N=5), medical (blue, N=10), and environmental (olive green, N=4) factors.

Supplementary Figure 3. Odds ratio [95% confidence intervals] from logistic models for risk of COVID-19 death (in blue) and non-COVID-19 death during the same period (in orange). Results are presented for sequentially adjusted models: demographic (Model 1), with additional adjustment for social (Model 2), health risk factors (Model 3), biological (Model 4), medical (Model 5), and environmental factors (Model 6).

Supplementary Figure 4: Receiver operating characteristic (ROC) curves from logistic regression models for the risk of non-COVID-19 death between 31 January and 21 September 2020. ROC curves are presented for a logistic model including (N=4) demographics covariates (grey) and the (N=12) factors consistently selected by the logistic LASSO (purple). Predictive performances were derived from a subsampling procedure (repeated independently 1,000 times) of 80% of the study population as training set to produce ROC curves and corresponding AUC in the validation set (remaining 20%). The ROC curve and AUC point estimate corresponds to mean performance across the 1,000 subsamples, and the coloured areas (and AUC ranges) reflect the 1st and 99th percentiles of the performances yielded across the subsamples.

Supplementary Table 1. Codes for (A) comorbidities using UK Biobank data coding 3 and 6 (self-report, UK Biobank fields 20001 and 20002) and linkage to Hospital Episode Statistics (ICD-9 and ICD-10) and (B) medication use at baseline (data coding 4, UK Biobank field 20003).

Supplementary Table 4. Odds ratio [95% confidence intervals], and p-values from logistic models for the probability of COVID-19 death (A) and non-COVID-19 death (B) in the full UK Biobank sample. Results are represented for sequentially adjusted models, where benchmark predictors are defined as demographic descriptors (D, Model 1), and models are additionally adjusted for social (S, Model 2), health risk (HRF, Model 3), biological (B, Model 4), medical (M, Model 5), and environmental factors (E, Model 6).
