

ESM Figure 3

The mock-PBS-DiR was done as the labeling of exosomes but without exosomes. 25 ml PBS with 1 μ M DiR was ultracentrifuged at 110,000g for 90 min (no extra washing step, to have as much free DiR as possible as control). The pellet was resuspended in 200 μ l PBS and injected in a mouse. As shown, the distribution pattern is very different than with exosomes, with majority of the signal originating from the GI-tract.
