Model

The system of ODEs describing the dynamic is given by:

$$\begin{split} S_{i}^{\prime} &= -\lambda_{s_{i}} - \phi_{i} S_{i} \left\{ \left(1 - b(t)\right) \left[\beta^{o} \sum_{j}^{6} c_{ij}(A_{i} + \xi I_{m_{i}}) \right] \right\} + \omega_{1} V_{1i} + \omega_{2} V_{2i} \\ &+ b(t) \left[\beta^{N} \sum_{j}^{6} c_{ij}(A_{i} + \xi I_{m_{i}}) \right] \right\} + \omega_{1} V_{1i} + \omega_{2} V_{2i} \\ L_{i} &= \phi_{i} S_{i} \left\{ \left(1 - b(t)\right) \left[\beta^{o} \sum_{j}^{6} c_{ij}(A_{i} + \xi I_{m_{i}}) \right] - b(t) \left[\beta^{N} \sum_{j}^{6} c_{ij}(A_{i} + \xi I_{m_{i}}) \right] \right\} \\ &+ \phi_{i} V_{1i} (1 - \epsilon_{1i}) \left\{ \left(1 - b(t)\right) \left[\beta^{o} \sum_{j}^{6} c_{ij}(A_{i} + \xi I_{m_{i}}) \right] \right\} \\ &+ b(t) \left[\beta^{N} \sum_{j}^{6} c_{ij}(A_{i} + \xi I_{m_{i}}) \right] \right\} - (1 - b(t)) \alpha^{o} L_{i} - b(t) \alpha^{N} L_{i} \\ A_{i}^{\prime} &= (1 - \rho) (1 - b(t)) \alpha^{o} L_{i} + (1 - \rho) b(t) \alpha^{N} L_{i} - (1 - b(t)) \gamma_{aR_{i}}^{o} A_{i} \\ &- b(t) \gamma_{aR_{i}}^{N} A_{i} \\ I'_{m_{i}} &= \rho (1 - b(t)) \alpha^{o} L_{i} + \rho b(t) \alpha^{N} L_{i} - (1 - b(t)) \gamma_{H_{i}}^{o} I_{m_{i}} - b(t) \gamma_{H_{i}}^{N} I_{m_{i}} \\ - (1 - b(t)) \gamma_{aR_{i}}^{o} I_{m_{i}} - b(t) \gamma_{mR_{i}}^{N} I_{m_{i}} \\ H_{i}^{\prime} &= (1 - b(t)) \gamma_{H_{i}}^{o} I_{m_{i}} + b(t) \gamma_{H_{i}}^{N} I_{m_{i}} - (1 - b(t)) \gamma_{RR_{i}}^{o} I_{m_{i}} + b(t) \gamma_{RR_{i}}^{N} I_{m_{i}} \\ H_{i}^{\prime} &= (1 - b(t)) \gamma_{aR_{i}}^{o} A_{i} + b(t) \gamma_{AR_{i}}^{N} A_{i} + (1 - b(t)) \gamma_{mR_{i}}^{o} I_{m_{i}} + b(t) \gamma_{mR_{i}}^{N} I_{m_{i}} \\ + (1 - b(t)) \gamma_{RR_{i}}^{o} H_{i} + b(t) \gamma_{RR_{i}}^{N} H_{i} \\ B_{i}^{\prime} &= (1 - b(t)) \gamma_{RR_{i}}^{o} A_{i} + b(t) \gamma_{RR_{i}}^{N} A_{i} + (1 - b(t)) \gamma_{mR_{i}}^{O} I_{m_{i}} + b(t) \gamma_{mR_{i}}^{N} I_{m_{i}} \\ + (1 - b(t)) \gamma_{RR_{i}}^{O} H_{i} + b(t) \gamma_{RR_{i}}^{N} H_{i} \\ V_{1i} &= \lambda_{s_{i}} - \phi_{i} V_{1i} (1 - \epsilon_{1i}) \left\{ (1 - b(t)) \left[\beta^{o} \sum_{j}^{6} c_{ij} (A_{i} + \xi I_{m_{i}}) \right] \right\} - \sigma \epsilon_{2_{i}} V_{1i} - \omega_{1} V_{1i} \\ V_{2i} &= \sigma \epsilon_{2_{i}} V_{1i} - \omega_{2} V_{2i} \\ \end{array}$$

For $i \in \{1,2,3,4,5,6\}$, where $\beta^N = \zeta \beta^O$.

Eq.SI1

The list of variables and assumptions is given in Table SI1.

Variable	Definition
S _i	Susceptible individuals in age group i
Li	Latently infected individuals in age group i
A _i	Asymptomatic individuals in age group i
I _{mi}	Symptomatic (mild) individuals in age group i
H _i	Hospitalized individuals in age group i
D _i	Deceased individuals in age group i
R _i	Recovered individuals in age group i
V _{1i}	Vaccinated individuals in age group i (first dose)
V _{2i}	Vaccinated individuals in age group i (second dose)
i ∈ {1,2,3,4,5,6}	Age groups: 0-9,10- 19, 20-39, 40-59, 60-79, 80+ years respectively
Assumptions	
1. Only susceptible	individuals, aged 10 years and older, will receive the vaccine
2. Immunity follows	s two steps: partial (receiving one dose) and full (receiving two doses)
3. The vaccine effic	acy is age-dependent (higher for teenagers and adults, lower for elderly)
4. The vaccine effic	acy is the same against wildtype variant and VOC
5. The second dose following the sug	is given after 112 days (in some predictive scenarios after 50 or 21 days), gestion announced by the Government of Ontario in March 2021
6. Immunity wanes days	from one dose of vaccine after 120 days and from two doses after 365
7. We assume that t vaccination proce	he coverages in Table 2 are reached by June 14, 2021, and continue the ass until 80% of the total population is vaccinated
8. We assume that a	ll non-wild type cases belong to B.1.1.7
9. VOC and wildtyp of cases from VO	e are both included in the transmission process, assuming that proportion C increases by time, following a sigmoidal function
10. The transmission	from VOC is assumed to be 1.5 higher than the original variant
11. Vaccine reduces infectious if the v	susceptibility. Partially vaccinated people can become infected and accine is not efficient
12. Only individuals	hospitalized might die from the infection

Table SI1: Table of the model's variables and assumptions

Parameter	Definition	Value	Ref.

Proportion of VOC cases

To capture the increasing trend of cases from VOC, we defined a time-dependent function (b(t)) following a sigmoid function. Fig. A1 shows the proportion of cases from VOC from data (red circles) and the function used to reproduce their trend (blue curve). According to data up to May 19, 2021 the proportion of cases from VOC in Toronto reached a maximum of 0.8 by May 11, 2021. Hence, we consider 80% to be the maximum of cases generated by the new variant.

Figure SI1: Sigmoidal function describing the growth of proportion of cases from VOC in Toronto. Scatter plot represents the proportion of VOC cases in Toronto from December 28, 2020 to May 11, 2021.

Data fitting

To calibrate the model's parameters, we employed cumulative and daily cases and deaths, and hospitalizations (**Figure SI2**). Using the Latin Hypercube Sampling (LHS), we generated 500 samples for the initial guess of each parameter using a normal distribution. Then, for each initial guess of parameter set, employed the fmincon function in the MATLAB optimization Toolbox¹⁴ to find the local minimum of the sum of squared differences between observed data and the model's estimates of daily confirmed cases and deaths, cumulative cases and deaths and hospitalizations. After finding the best parameter set for each sample, we evaluated the mean value and the standard deviation, obtaining the confidence interval where our parameters lie.

Figure SI2: Calibration of parameters calibration using Least Square Method. We used cumulative and daily cases and deaths, and hospitalizations between December 28, 2020 and May 19, 2021. Red line indicates the mean value; Blue and yellow lines indicate the upper and lower bound of the confidence interval.

Permutations of model's analysis

All the scenarios used for the projections are shown in Figure SI3. Each scenario is described by taking one element in each column.

Baseline for analyses										
10-19 years 20-39 years 40-59 years 60-79 years 80 + years NPIs Lift Level NPIs Lift Date										
20%	60%	70%	80%	80%	None	Never				

Figure SI3: Outward-facing model coverages and base line for model's analysis. All these coverages are reached by June 14, 2021. In brackets, we report the daily doses. Each scenario is described by taking one element in each column.

Uncertainty of the parameters

Figure SI4: Variation of hospitalizations with respect to the parameters estimated in the confidence interval

Contact matrix

We used the total contact matrix from a recent Canadian study³. However, the age groups used in this study were defined by a 5-year band from 0 to 80+. Our model is using larger age groups, then it was necessary to aggregate the original contact matrix in less groups.

Let's define P_j the population size of age group $j \in \{1,2,3, ..., 17\}$, where 1 = 0 - 4 years, 2 = 5 - 9 years, ..., 17 = 80 + years. To better approximate the contact rates, we calculated, from the original 17x17 matrix (M_{ij}), the total contacts that an age group has with all the other age groups. To obtain this, we multiplied all the age groups by their own population size, i.e. $m_{ij} \times P_j$. Then, to aggregate some age groups, we averaged the total contacts as follows:

• For same ages belonging to new aggregation: we summed up the diagonal entries of the submatrix related to the age groups to aggregate and the average of the mixed contacts $(\hat{c}_{ii} = \sum m_{ii} + \sum \frac{m_{ij} + m_{ji}}{2})$. For example, the new contact of the aggregated group 0-9, given by group 1 and 2, will be $m_{11} + m_{22} + \frac{m_{12} + m_{21}}{2}$

• For different ages aggregation: we summed up the average of the mixed contacts $(\hat{c}_{ij} = \sum \frac{m_{ij} + m_{ji}}{2})$. For example, the new contact of the aggregated group 0-9 and 10-19, given by group 1, 2, 3 and 4, will be $\frac{m_{13} + m_{31}}{2} + \frac{m_{14} + m_{41}}{2} + \frac{m_{23} + m_{32}}{2} + \frac{m_{24} + m_{42}}{2}$

Once we reduced the total contacts into a smaller matrix, we re-parametrized each entry of the new age group dividing the obtained contacts by the population size of the aggregate age group (i.e., $c_{ij} = \hat{c}_{ij} / \sum P_j$). Table SI3 represents the compacted matrix.

		Age participants										
		0-9	10-19	20-39	40-59	60-79	80+					
	0-9	2.61	0.55	0.59	0.73	0.22	0.04					
	10-19	0.58	3.28	0.77	0.95	0.22	0.11					
Age	20-39	2.23	2.72	3.35	3.82	1.50	0.66					
contacts	40-59	2.12	2.56	2.94	2.49	1.65	1.12					
	60-79	0.41	0.39	0.75	1.08	1.22	1.05					
	80+	0.02	0.05	0.09	0.20	0.29	0.58					

Table SI3: Contact matrix

RESULTS

Reproduction number R_c

Figure SI5: Contour plots of R_c assuming that the following coverages reached for age groups 10-19, 60-79 and 80+ years are 20%, 80%, and 90%, respectively, when the NPIs level reopening is (A) none, (B) partial, (D) total and (E) pre-pandemic. As expected, as the vaccination coverage increases, the values of the reproduction number decrease. Also, we observe that with the lowest reopening level, to reduce the reproduction number below 1, it is sufficient to vaccinate age groups 20-39 and 40-59 years above 60% and 62%, respectively. On the other hand, a relaxation of NPIs and increase in contacts as in NPIs partial reopening, the R_c will always be greater than 1. Similar results, but higher R_c , are shown with NPIs pre-pandemic reopening (C).

С

Projections

Identification of age group that minimizes cases, deaths and hospitalizations

Table SI4: Percentage change of cumulative cases and deaths with respect to the base line NPIs no reopening in SI Figure SI3 with partial reopening in September, when age groups 60-79 and 80+ reached coverages 80%, 90% by June 14. Cases and deaths are reported comparing different coverages for age group 10-19 years, assuming 40-59 years fixed at 70% coverage (top table) and comparing different coverages for age group 40-59 years, assuming 10-19 years fixed at 20% coverage (bottom table). The second dose is given at a rate of 1/112 days⁻¹

Sensitivity Analysis

Using the Latin Hypercube Sampling/Partial Rank Correlation Coefficient (*LHS/PRCC*) we conducted sensitivity analysis on the parameters related to vaccination as well as infection-related parameters.

SENSITIVITY ANALYSIS								
PARAMETERS	DEFINITION	PRCC						
		CASES	DEATHS	HOSPITALIZATION (50 days after reopening in June)				
σ	Rate at which second dose is distributed	-0.9409	-0.9409	-0.9638				
λ_2	Daily doses age group 10- 19	0.01411	0.01411	0.02773				
λ_3	Daily doses age group 20- 39	-0.8897	-0.8897	-0.923				
λ_4	Daily doses age group 40- 59	-0.8206	-0.8206	-0.9088				
λ_5	Daily doses age group 60- 79	-0.1792	-0.1792	-0.4888				
λ_6	Daily doses age group 80+	-0.03836	-0.03836	-0.1357				
SENSITIVITY AN	NALYSIS							
PARAMETERS	DEFINITION	PRCC						
		CASES	DEATHS	HOSPITALIZATION (50 days after reopening in September)				
σ	Rate at which second dose is distributed	-0.9409	-0.9409	-0.9638				
λ_2	Daily doses age group 10- 19	0.01411	0.01411	0.02773				
λ_3	Daily doses age group 20- 39	-0.8897	-0.8897	-0.923				
λ_4	Daily doses age group 40- 59	-0.8206	-0.8206	-0.9088				
λ_5	Daily doses age group 60- 79	-0.1792	-0.1792	-0.4888				
λ_6	Daily doses age group 80+	-0.03836	-0.03836	-0.1357				

Table SI11: PRCC on cumulative cases and deaths, investigating vaccine-related parameters.

Table SI11 shows the PRCCs of the sampled parameters λ_i , $i \in \{2,3,4,5,6\}$, and σ , the daily doses in age group i, and the rate of receiving the second dose, respectively, on the cumulative cases and deaths. We observe that the age groups 3 and 4, namely, 20-39 and 40-59 years present the highest PRCC among the daily doses, suggesting that an increased vaccine

coverage of these age groups leads to the largest reduction in cases and deaths. Moreover, σ is negatively correlated to cases and deaths, suggesting that if this rate is small, hence the time between doses is longer, cases and deaths will increase. Similar results are visible for the hospitalizations reported 50 days after reopening in June.

Table SI12 shows the PRCC of some of the infection-related parameters on the model outcomes. Increase of contact, susceptibility of adults aged between 20 and 59 years show a significant positive correlation on deaths and cases, suggesting that reopening stages and higher susceptibility of adults will generate an increase of the infection,

SENSITIVITY ANALYSIS							
PARAMETERS	DEFINITION	PRCC					
		CASES	DEATHS				
C _{inc}	Percentage increase of contacts	0.6878	0.6878				
ϕ_1	Susceptibility age group 0-9	0.4791	0.4791				
ϕ_2	Susceptibility age group 10-19	0.4946	0.4946				
ϕ_3	Susceptibility age group 20-39	0.9539	0.9539				
ϕ_4	Susceptibility age group 40-59	0.9158	0.9158				
ϕ_5	Susceptibility age group 60-79	0.3994	0.3994				
ϕ_6	Susceptibility age group 80+	0.106	0.106				

 Table SI12: PRCC on cumulative cases and deaths, investigating infection-related parameters.

Cases data until December 2021

Figure SI9: Daily cases reported in Toronto from December 2020 to December 2021¹⁵ (green). The dashed lined represents the end of the period of time used to calibrate the model. The curves represent the model outcomes, with highest coverage among adults, under the following scenarios: total reopening in August with second dose given 21 days after first dose; total reopening in September with second dose given 112 days after first dose; partial reopening in September with second dose given 21 days after first dose; partial reopening in September with second dose given 112 days after first dose; partial reopening in September with second dose given 112 days after first dose; partial reopening in September with second dose given 112 days after first dose.

Data following the period of time used for the model calibration show similar trend to our model prediction, with a decrease trend until August 15, followed by a slight increase. towards the end of 2021, we observe a sharp increase, attributable to the emergence of Omicron.
